THE HUMAN BATTERY™ PROJECT

Your First Steps

BEFORE DAY ONE

You know what you should be doing and you do some of it. This turns sometimes into every day.

START HERE

Three things to do today

You do not start the protocol yet. These are the things that have to be true before day 1. The first one is the one that takes longest, so it goes first.

1

Order your Omega-3 kit today

Order a dried-blood-spot
Omega-3 Index
test. The specification is the whole of it: a lab that reports EPA plus DHA as a percentage of red blood cell fatty acids, which is the defined measurement the panel uses. Any lab reporting that number qualifies. OmegaQuant originated the measurement and sells one. You order it yourself and it comes to you. We take no commission on it.

Do this first. Do it today. It takes the longest of anything on this list. The kit takes three to five days to reach you. Then you mail it back. Then the lab runs it. Allow two to four weeks from ordering to result. Everything else here takes a week at most.

Order two at once.

You need one now and one at day 90, sellers usually discount the pair, and the second one is already in your drawer when day 90 comes.

Order the version that also reports the AA to EPA ratio.

The cheaper option reports the Omega-3 Index on its own. The AA to EPA ratio is on your panel and is hard to obtain anywhere else, so the cheaper option costs you a marker.

2

Book your blood test

Book a walk-in blood draw yourself. The specification: a draw site that accepts patients without a physician order, lets you request a custom panel from a marker list, and sends to a national reference laboratory. Several national chains meet this and most cities have one.

Do not eat for 12 hours before. Go in the morning.

Water is fine. Some of these numbers move as the day goes on, so a test at 11am does not match a test at 7am. Pick a morning time. Book the same time again at day 90.

Your tier document lists what to ask for. Take the list with you.

Your Human Battery Score is identical at every panel. Higher panels add context, not points.

3

Prick your finger and mail the card

When the kit comes, prick your finger, put the drop on the card, and mail it the same day. The envelope is already paid for.

This is the one that decides whether you can start.

The card has to be in the mail before day 1. The result comes back in your first two weeks and that is fine. The drop is fixed the moment you take it, so a result that shows up later is still your day 0 number.

Tell us when it is in the mail. There is a button in your portal.

THEN THESE

Three things for this week

None of these are urgent. Do them before day 1 and you will be ready.

4

Read your protocol once

It is in your portal under Program. Read it once. Do not try to learn it. You are not starting yet.

Every day has the same shape: light, water, moving, food, moving, light, dark. Your tier sets how much. It does not change the order.

5

Get a few things

Amber or red glasses for after dark. An unrefined salt with a full trace-mineral profile, not refined sodium chloride. A water bottle you will actually use. That is enough to begin.

The full list is in your tier document. Only the glasses are urgent.

6

Put the weekly call in your calendar

One hour. Everyone together. Every week. The day, the time and the link are in your portal under Calls.

You can send a question before the call and it gets answered first.

Why the kit comes first

The Omega-3 Index moves more than anything else we measure. Red cell walls rebuild over about four months, so ninety days is long enough to change it and short enough that the change is yours.

That only works if we have a day 0 number to compare against. Start without one and it is gone. No test later brings it back.

> **Mailed, not answered.** What has to be true before day 1 is that the card is in the mail. Not that the result is back. The result comes in your first two weeks and that is fine.
>
> **If it is not mailed in time**, your portal offers to move your start to the next date. You lose nothing and it costs nothing. Take the offer. It beats starting blind.
>
> **If you start without it anyway**, you can still take the drop in your first two weeks and it counts. We store the day you took it, so your day 90 comparison says which day it was instead of pretending it was day 0.

DAY ONE

What the first day looks like

INTERMEDIATE

Outside within 30 minutes of waking. Fifteen minutes minimum, twenty when cloudy. Face east. Barefoot on the ground when you can.

Then the morning glass. Your eating window is 8am to 5pm.

Fifteen minutes of sun on your arms and face in the afternoon. Outside for the last fifteen minutes of light. Amber lenses from sunset.

> **The rule that matters most:** light before food, every single day. Do not eat until you have been outside.

THE HONEST PART

What this is, and is not

The Human Battery Project is an educational wellness program, not medical treatment. It does not diagnose or treat any condition and does not replace your physician.

Any laboratory result outside the reference range is referred to a physician. Every time.

If you take prescription medication, review any change to your eating window, and any sauna or cold exposure, with your prescriber before starting. Never adjust a medication on your own because of anything in this document.

Stop and seek medical care for chest pain, fainting, shortness of breath at rest, or any new symptom that concerns you.

Never manipulate potassium or other electrolytes to try to change your body's charge. Balance and correction of a genuine deficiency only.

> **We do not promise outcomes.** We measure at both ends and show you exactly what changed.
